AIMS AND SCOPE

Virus Research provides a means of rapid publication for original papers on fundamental research concerning virus structure, replication, and pathogenesis. These include reports describing virus morphology, the function and antigenic analysis of virus structural components, virus genome structure and expression, analysis of virus replication processes, effects of viruses on their host cells, and the pathogenesis of virus infections. Occasional review articles, book reviews, and meeting reports are also published.

INSTRUCTIONS TO AUTHORS

Submission of a paper to *Virus Research* implies:

- (1) that it has not previously been published (except in abstract form) and that it is not being submitted for publication elsewhere;
- (2) the transfer of the copyright from the author to the Publisher.

Papers and original figures should be submitted together with one copy and accompanied by a letter of transmittal to one of the Editors-in-Chief.

Dr. B.W.J. Mahy, *Virus Research*, Animal Virus Research Institute, Pirbright, Woking, Surrey GU24 0NF, U.K.

Dr. R.W. Compans, Editorial Office, *Virus Research*, University of Alabama at Birmingham, P.O. Box 319A, Volker Hall, Birmingham, AL 35294, U.S.A.

Types of papers

- (1) Full-length papers generally not exceeding 25 typewritten pages.
- (2) Short communications not exceeding 1500 words or equivalent space including figures and tables. These must be brief definitive reports and *not* preliminary findings.
- (3) Reviews will be published following invitation from an Editor-in-Chief.

Announcements of meetings and courses will be included at the discretion of the Editors and the Publisher.

MATHEMATICAL MODELLING APPROACH FOR REVEALING PHYLOGENETIC RELATIONSHIPS BETWEEN ANTIGENICALLY RELATED AVIAN PARAMYXOVIRUSES (PMV)

MICHAEL LIPKIND AND NAPHTALI RISHE. Kimron Veterinary Institute, Beit Dagan, Israel and School of Computer Science, Florida Int. University, Miami, Florida 33199, USA.

Within avian PMV group numbering to date 9 antigenic serotypes, diverse multidirectional antigenic interconnections have been found being displayed by both haemagglutination and neuraminidase inhibition tests. A combinatorial mathematical model published recently (Rishe & Lipkind, 1987) described the complicated antigenic relationships including phenomenon of the one-way asymmetric cross reactivity. Further development of the mathematical model resulted in elaborating approach for revealing the ancestry between the compared antigenically related viruses. This permitted the construction of a phylogenetic tree based on computer-assisted combinatorial consideration (theory of trees). Treatment of the serological cross reaction data involving all the avian PMV serotypes and based on combinatorics or provisional triples ("parent-child-grandchild") has revealed 12 triple combinations (from the whole total of 788 possible ones) which satisfied the postulated criteria of ancestry. Although an individual triple alone does not tell which member of the triple (serotype) plays the role of parent, child and grandchild the above global analysis of the whole totality of all the data provided for only one probable solution. The analysis revealed definite phylogenetic connections between the members of the avian PMV group which has not yet been properly established taxonomically.

ANTIGENIC VARIATION ON THE INTERNAL PROTEIN OF MEASLES VIRUS :
IDENTIFICATION AND EXPRESSION
OF THE INDIVIDUAL EPITOPES IN BACTERIA

R. Buckland, P. Giraudon and T.F. Wild

Measles virus is a childhood infection. The severity of the disease may differ in various regions. Although measles is considered as a monotypic virus, recent observations have suggested problems with vaccination. To investigate this, we isolated a number of measles virus strains from Africa and France. We examined them with a bank of monoclonal antibodies against the two glycoproteins (haemagglutinin and fusion) and two internal proteins (nucleoprotein and matrix). The only antigenic variation was on the nucleoprotein. Three distinct epitopes were identified with the nucleoprotein monoclonal antibodies. One was found on all strains, whereas the other two varied. To define these epitopes, we cloned the nucleoprotein gene into the PRIT vector and expressed it as a fusion protein in *E. Coli*. All three epitopes could be identified by Western blotting on the recombinant protein. Deletions of the nucleoprotein gene were used to produce fragments which were subsequently expressed in *E. Coli* and examined for the presence of the three epitopes. We have shown that the two variable sites are at the C-terminus of the protein (a.a. 457-480 and 519-525); whereas the non-variable site was closer to the N-terminal end (a.a. 122-150). The preparation of antigenic probes, as shown here, will enable a more detailed study of the epidemiology of measles and its associated infections.
