Devices related to a conductive fabric sensor are provided. A device can comprise an insulting and flexible fabric substrate, a central transmitting electrode on a top surface of the insulting and flexible fabric substrate, a plurality of receiving electrodes surrounding the central transmitting electrode and connected to the central transmitting electrode, and a power supply configured to generate a respective electric field between the central transmitting electrode and each receiving electrode of the plurality receiving electrodes.

THREE DIMENSIONAL TOUCH CONDUCTIVE FABRIC

BACKGROUND

Wearable electronics have become widespread in consumer markets due to their convenience and for being lightweight. Functionality of wearable electronics continues to increase as technology becomes smaller and wearable electronics are integrated for use in routine activities. However, wearable electronics are currently designed to mimic the form of other devices that are generally bulky and hard, such as watches or bracelets. Watches have conventionally made straps from rubber, or metal and this has been carried through with smartwatches.

With the creation of conductive fabric and conductive thread, electronics may be intertwined with clothing or other applications of fabric. Conductive fabric used in watch straps can provide additional functionality, which would otherwise be limited by the usable space on a watch face. Worn on other parts of the body, conductive fabric can be used to interact with surrounding electronics. The simple transition from rigid components to cloth allows for pressure sensing, multi-finger touch sensing, and non-contact three dimensional (3D) sensing.

BRIEF SUMMARY

Embodiments of the subject invention provide a conductive textile that can be used to sense the motion of a hand in three dimensions, without the need of contact between the hand and the textile. Conductive threads and other electrodes can be woven into the fabric, sewn in, or attached by other means. The three dimensional (3D) conductive fabric can be flexible and comfortably integrated with clothing or used on a watch strap. The 3D conductive fabric can also be used in conjunction with other touch textiles, such as a multi-touch capacitive sensor and/or a resistive touch sensor.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1 is a diagram of a central transmitter electrode in a snake configuration surrounded by four receiver electrodes, each in a zigzag configuration.

FIG. 2 is a diagram of a central transmitter electrode made of individual electrodes in a grid formation and four receiver electrodes each made of individual electrodes in a grid formation.

FIG. 3a is a diagram of a flexible dielectric material on a substrate. FIG. 3b is a diagram illustrating the flexible nature of the three dimensional conductive fabric.

FIG. 4 is a diagram illustrating the electric field lines from the central transmitter electrode to four surrounding receiver electrodes.

DETAILED DESCRIPTION

The following disclosure and exemplary embodiments are presented to enable one of ordinary skill in the art to make and use the three-dimensional conductive fabric according to the subject invention. Various modifications to the preferred embodiment will be readily apparent to those skilled in the art and the generic principles herein may be applied to other embodiments. Thus, three-dimensional conductive fabric is not intended to be limited to the embodiments shown but is to be accorded the widest scope consistent with the principles and features described herein.

A capacitive textile can be used for the detection of an object passing near the capacitive textile. As seen in FIG. 1, a central transmitter can comprise a conductive thread that is woven, sewn, or otherwise attached to a top surface of a fabric substrate. In some embodiments the flexible substrate comprises an insulating material. In certain embodiments, the central transmitter comprises a conductive thread configured in a snake pattern. The central transmitter is surrounded by receiving electrodes, each being formed from a respective piece of conductive thread and in a zigzag pattern. The central transmitter and the receiving electrodes can be connected to sensors for sensing an electrical current, a magnetic field, electrical field, or a capacitance.

The transmitter electrode/central transmitter can vary in size as long as the material does not provide too much electrical resistance. In certain embodiments, the respective length and width dimensions of a rectangular transmitter electrode are each in a range of 1 to 24 inches. Each receiver electrode can have smaller dimensions than the transmitter electrode. In certain embodiments, each receiver electrode has a length or width equal to a respective length or width of the transmitter electrode, but the other dimension of the receiver electrode can be reduced to ¼ of the respective other dimension of the transmitter electrode. The transmitter electrode and the receiver electrodes can each comprise a thread coated in a metal powder (e.g. shaved metal pieces), a thread twisted with a metal wire, a conductive paint (and applied in solid fill or lattice), or a flexible printed circuit board (PCB) with a copper pattern.

The conductive thread can be sewn or woven into regular cloth in any pattern necessary. The conductive thread can be electrically insulated to prevent it from short circuiting when in contact with another wire. An insulating coating can be applied to the conductive thread including cloth, plastic, or resin depending on the location and the use of the particular area. The conductive thread can be flexible to be comfortably integrated with clothing, but strong enough to endure the stress from everyday use and washing.

The conductive fabric does not have to be limited to a single strand wire wrapped in fabric (conductive thread) and can be any conductive material that can be attached to fabric. Small electrodes can be placed between layers of fabric. This may include thin, flexible metal electrodes, metal coated plastic, or a plurality of small electrodes bundled together.

In another embodiment, the central transmitting electrode can be in the form of a wire grid, as seen in FIG. 2. The receiving electrodes can also comprise wire electrodes in a grid formation on a top surface of the fabric substrate.

As shown in FIG. 2, the central transmitter can comprise individual electrodes configured in a longitudinal and latitudinal directions. This permits the sensor to bend and conform to the surface of the fabric substrate. The electrode grid forms capacitors at the intersection of the longitudinal and latitudinal electrodes. When a person’s finger is near the fabric, the capacitance at the intersection can be measured to determine where the user’s finger is on the grid. This method permits multiple objects to be tracked at the same time.

FIG. 3a shows a plan view of a dielectric material on a substrate. FIG. 3b is a diagram illustrating the flexible nature of the three dimensional conductive fabric.

As shown in FIG. 3a, the dielectric material can be in the form of a foil disposed on the fabric substrate. The
Pressure sensing transducers can operate through a resistive or capacitive approach. The resistive approach uses a grid system made of conductive material on two separate substrates. Conductive threads being sewn in parallel in two different pieces of fabric. The two different pieces of fabric can be attached with their traces being orthogonal to each other and having an insulating material in between. A nonconductive fabric that has small conductive material in it can be compressed, allowing a conductive path to form. The wires at both ends of this material would then be electrically connected and the point of contact can be measured.

For a capacitive approach, a grid of conductive traces can be disposed on the fabric substrate, and capacitors can be formed at a position in which the traces overlap. When a conductive object is near the grid, the capacitance is changed. Each intersection can be measured to determine where the user’s finger is on the grid.

In one embodiment, the three dimensional conductive fabric is disposed on a wristband or glove. The wristband or glove can interact with a host device through the three dimensional conductive fabric. In another embodiment, the three dimensional conductive fabric is embodied into clothing and interacts with a wireless device. By applying the three dimensional conductive fabric to clothing including wrist bands or glove, a computing device can be configured to accept hand gestures or body movements as inputs.

The methods and processes described herein can be embodied as code and/or data. The software code and data described herein can be stored on one or more machine-readable media (e.g., computer-readable media), which may include any device or medium that can store code and/or data for use by a computer system. When a computer system and/or processor reads and executes the code and/or data stored on a computer-readable medium, the computer system and/or processor performs the methods and processes embodied as data structures and code stored within the computer-readable storage medium.

It should be appreciated by those skilled in the art that computer-readable media include removable and non-removable structures/devices that can be used for storage of information, such as computer-readable instructions, data structures, program modules, and other data used by a computing system/environment. A computer-readable medium includes, but is not limited to, volatile memory such as random access memories (RAM, DRAM, SRAM); and non-volatile memory such as flash memory, various read-only memories (ROM, PROM, EPROM, EEPROM), magnetic and ferromagnetic/ferroelectric memories (MRAM, FeRAM), and magnetic and optical storage devices (hard drives, magnetic tape, CDs, DVDs); network devices; or other media now known or later developed that are capable of storing computer-readable information/data. Computer-readable media should not be construed or interpreted to include any propagating signals. A computer-readable medium of the subject invention can be, for example, a compact disc (CD), digital video disc (DVD), flash memory device, volatile memory, or a hard disk drive (HDD), such as an external HDD or the HDD of a computing device, though embodiments are not limited thereto. A computing device can be, for example, a laptop computer, desktop computer, server, cell phone, or tablet, though embodiments are not limited thereto.

A greater understanding of the present invention and of its many advantages may be had from the following examples, given by way of illustration. The following examples are illustrative of some of the methods, applications, embodiments and variants of the present invention. They are, of
course, not to be considered as limiting the invention. Numerous changes and modifications can be made with respect to the invention.

It should be understood that the examples and embodiments described herein are for illustrative purposes only and that various modifications or changes in light thereof will be suggested to persons skilled in the art and are to be included within the spirit and purview of this application.

All patents, patent applications, provisional applications, and publications referred to or cited herein are incorporated by reference in their entirety, including all figures and tables, to the extent they are not inconsistent with the explicit teachings of this specification.

What is claimed is:

1. A conductive fabric sensor, comprising:
   a first flexible fabric substrate comprising a first surface and a second surface opposite to the first surface;
   a first dielectric layer disposed on, and in direct physical contact with, a central area of the first surface of the first flexible fabric substrate;
   a second dielectric layer, a third dielectric layer, a fourth dielectric layer, and a fifth dielectric layer surrounding the first dielectric layer and disposed on, and in direct physical contact with, the first surface of the first flexible fabric substrate;
   a sixth dielectric layer disposed on, and in direct physical contact with, the second surface of the flexible substrate and having an area at least as great as that of the first dielectric layer;
   a central transmitting electrode on the first dielectric layer;
   a plurality of receiving electrodes surrounding the central transmitting electrode, and being electrically connected to the central transmitting electrode, the plurality of receiving electrodes comprising four receiving electrodes respectively disposed on the second dielectric layer, the third dielectric layer, the fourth dielectric layer, and the fifth dielectric layer;
   a power supply configured to generate a respective electric field between the central transmitting electrode and each receiving electrode of the plurality receiving electrodes; and
   a plurality of resistive pressure sensing transducers comprising conductive threads sewn in parallel in the first flexible fabric substrate and a second flexible fabric substrate, the first flexible fabric substrate and the second flexible fabric substrate being attached with traces thereof being orthogonal to each other and having a compressed insulating material therebetween, and the compressed insulating material comprising a conductive material therewithin having wires at both ends thereof.

2. The conductive fabric sensor of claim 1, wherein the first dielectric layer having a rectangular shape, when viewed from above the first surface, with a first side, a second side, a third side, and a fourth side, the second dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the first side of the first dielectric layer, the third dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the second side of the first dielectric layer, the fourth dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the third side of the first dielectric layer, the fifth dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the fourth side of the first dielectric layer, a width of the second dielectric layer being the same as a length of the first side of the first dielectric layer, a width of the third dielectric layer being the same as a length of the second side of the first dielectric layer, a width of the fourth dielectric layer being the same as a length of the third side of the first dielectric layer, a width of the fifth dielectric layer being the same as a length of the fourth side of the first dielectric layer, a thickness of the first dielectric layer being about 0.05 millimeters (mm), a thickness of the second dielectric layer being about 0.05 mm, a thickness of the third dielectric layer being about 0.05 mm, a thickness of the fourth dielectric layer being about 0.05 mm, and a thickness of the fifth dielectric layer being about 0.05 mm.

3. The conductive fabric sensor of claim 1, wherein the conductive fabric sensor being disposed on a wristband or a glove.

4. The conductive fabric sensor of claim 1, further comprising:
   a sensor configured to sense a respective capacitance between the central transmitter and each receiving electrode of the plurality of receiving electrodes.

5. The conductive fabric sensor of claim 1, wherein the first dielectric layer, the second dielectric layer, the third dielectric layer, the fourth dielectric layer, the fifth dielectric layer, and the sixth dielectric layer all comprising a planar foil.

6. The conductive fabric sensor of claim 1, comprising:
   A computer-based system of motion sensing using a conductive fabric to transmit an input for a computing device, the system comprising:
   the conductive fabric sensor according to claim 1, the conductive fabric sensor being configured to be worn on a body; and
   a non-transitory computer-readable medium comprising instructions that when executed causes at least one processor to translate movements of a body as inputs to the conductive fabric sensor.

7. A conductive fabric sensor, comprising:
   a first flexible fabric substrate comprising a first surface and a second surface opposite to the first surface;
   a first dielectric layer disposed on, and in direct physical contact with, a central area of the first surface of the first flexible fabric substrate;
   a second dielectric layer, a third dielectric layer, a fourth dielectric layer, and a fifth dielectric layer surrounding the first dielectric layer and disposed on, and in direct physical contact with, the first surface of the first flexible fabric substrate;
   a sixth dielectric layer disposed on, and in direct physical contact with, the second surface of the flexible substrate and having an area at least as great as that of the first dielectric layer;
   a central transmitting electrode on the first dielectric layer;
   a plurality of receiving electrodes surrounding the central transmitting electrode, each receiving electrode of the plurality of receiving electrodes comprising a wire electrode in a zig zag pattern.
trodes being woven or sewn onto the flexible fabric substrate and the plurality of receiving electrode of the plurality receiving electrodes; and

4. A plurality of resistive pressure sensing transducers comprising conductive threads sewn in parallel in the first flexible fabric substrate and a second flexible fabric substrate, the first flexible fabric substrate and the second flexible fabric substrate being attached with traces thereof being orthogonal to each other and having a compressed insulating material therebetween, and the compressed insulating material comprising a conductive material therewithin having wires at both ends thereof; a first dielectric layer having a rectangular shape, when viewed from above the first surface, with a first side, a second side, a third side, and a fourth side, the second dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the first side of the first dielectric layer, the third dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the second side of the first dielectric layer, the fourth dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the third side of the first dielectric layer, the fifth dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the fourth side of the first dielectric layer, a width of the second dielectric layer being the same as a length of the first side of the first dielectric layer, a width of the third dielectric layer being the same as a length of the second side of the first dielectric layer, a width of the fourth dielectric layer being the same as a length of the third side of the first dielectric layer, a width of the fifth dielectric layer being the same as a length of the fourth side of the first dielectric layer, a thickness of the first dielectric layer being about 0.05 millimeters (mm), a thickness of the second dielectric layer being about 0.05 mm, a thickness of the third dielectric layer being about 0.05 mm, a thickness of the fourth dielectric layer being about 0.05 mm, and a thickness of the fifth dielectric layer being about 0.05 mm.

5. The conductive fabric sensor of claim 4, further comprising:

a sensor configured to sense a respective capacitance between the central transmitter and each receiving electrode of the plurality receiving electrodes.

6. The conductive fabric sensor of claim 4, comprising:

a first dielectric layer disposed on, and in direct physical contact with, a central area of the first surface of the first flexible fabric substrate; a second dielectric layer, a third dielectric layer, a fourth dielectric layer, and a fifth dielectric layer surrounding the first dielectric layer and disposed on, and in direct physical contact with, the first surface of the first flexible fabric substrate; a sixth dielectric layer disposed on, and in direct physical contact with, the second surface of the flexible substrate and having an area at least as great as that of the first dielectric layer; a central transmitting electrode on the first dielectric layer and configured in a grid pattern; a plurality of receiving electrodes surrounding the central transmitting electrode, each receiving electrode of the plurality receiving electrodes comprising a wire electrode configured in a grid pattern, and the plurality of receiving electrodes comprising four receiving electrodes respectively disposed on the second dielectric layer, the third dielectric layer, the fourth dielectric layer, and the fifth dielectric layer; a power supply configured to generate a respective electric field between the central transmitting electrode and each receiving electrode of the plurality receiving electrodes; a sensor configured to sense a respective capacitance between the central transmitter and each receiving electrode of the plurality receiving electrodes; and a plurality of resistive pressure sensing transducers comprising conductive threads sewn in parallel in the first flexible fabric substrate and a second flexible fabric substrate, the first flexible fabric substrate and the second flexible fabric substrate being attached with traces thereof being orthogonal to each other and having a compressed insulating material therebetween, and the compressed insulating material comprising a conductive material therewithin having wires at both ends thereof; the central transmitting electrode and the plurality of receiving electrodes being woven or sewn onto the first flexible fabric substrate, the conductive fabric sensor being disposed on a wristband or a glove, the first dielectric layer having a rectangular shape, when viewed from above the first surface, with a first side, a second side, a third side, and a fourth side, the second dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the first side of the first dielectric layer, the third dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the second side of the first dielectric layer, the fourth dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the third side of the first dielectric layer, the fifth dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the fourth side of the first dielectric layer, a width of the second dielectric layer being the same as a length of the first side of the first dielectric layer, a width of the third dielectric layer being the same as a length of the second side of the first dielectric layer, a width of the fourth dielectric layer being the same as a length of the third side of the first dielectric layer, a width of the fifth dielectric layer being the same as a length of the fourth side of the first dielectric layer, a thickness of the first dielectric layer being about 0.05 millimeters (mm), a thickness of the second dielectric layer being about 0.05 mm, a thickness of the third dielectric layer being about 0.05 mm, a thickness of the fourth dielectric layer being about 0.05 mm, and a thickness of the fifth dielectric layer being about 0.05 mm.

9. The conductive fabric sensor of claim 8, further comprising:

a sensor configured to sense a respective capacitance between the central transmitter and each receiving electrode of the plurality receiving electrodes.

10. The conductive fabric sensor of claim 8, comprising:

a first flexible fabric substrate comprising a first surface and a second surface opposite to the first surface; a first dielectric layer disposed on, and in direct physical contact with, a central area of the first surface of the first flexible fabric substrate; a second dielectric layer, a third dielectric layer, a fourth dielectric layer, and a fifth dielectric layer surrounding the first dielectric layer and disposed on, and in direct physical contact with, the first surface of the first flexible fabric substrate; a sixth dielectric layer disposed on, and in direct physical contact with, the second surface of the flexible substrate and having an area at least as great as that of the first dielectric layer; a central transmitting electrode on the first dielectric layer and configured in a grid pattern; a plurality of receiving electrodes surrounding the central transmitting electrode, each receiving electrode of the plurality receiving electrodes comprising a wire electrode configured in a grid pattern, and the plurality of receiving electrodes comprising four receiving electrodes respectively disposed on the second dielectric layer, the third dielectric layer, the fourth dielectric layer, and the fifth dielectric layer; a power supply configured to generate a respective electric field between the central transmitting electrode and each receiving electrode of the plurality receiving electrodes; a sensor configured to sense a respective capacitance between the central transmitter and each receiving electrode of the plurality receiving electrodes; and a plurality of resistive pressure sensing transducers comprising conductive threads sewn in parallel in the first flexible fabric substrate and a second flexible fabric substrate, the first flexible fabric substrate and the second flexible fabric substrate being attached with traces thereof being orthogonal to each other and having a compressed insulating material therebetween, and the compressed insulating material comprising a conductive material therewithin having wires at both ends thereof; the central transmitting electrode and the plurality of receiving electrodes being woven or sewn onto the first flexible fabric substrate, the conductive fabric sensor being disposed on a wristband or a glove, the first dielectric layer having a rectangular shape, when viewed from above the first surface, with a first side, a second side, a third side, and a fourth side, the second dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the first side of the first dielectric layer, the third dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the second side of the first dielectric layer, the fourth dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the third side of the first dielectric layer, the fifth dielectric layer having a rectangular shape, when viewed from above the first surface, and facing the fourth side of the first dielectric layer, a width of the second dielectric layer being the same as a length of the first side of the first dielectric layer, a width of the third dielectric layer being the same as a length of the second side of the first dielectric layer, a width of the fourth dielectric layer being the same as a length of the third side of the first dielectric layer, a width of the fifth dielectric layer being the same as a length of the fourth side of the first dielectric layer, a thickness of the first dielectric layer being about 0.05 millimeters (mm), a thickness of the second dielectric layer being about 0.05 mm, a thickness of the third dielectric layer being about 0.05 mm, a thickness of the fourth dielectric layer being about 0.05 mm, and a thickness of the fifth dielectric layer being about 0.05 mm.
a thickness of the first dielectric layer being about 0.05 millimeters (mm),
a thickness of the second dielectric layer being about 0.05 mm,
a thickness of the third dielectric layer being about 0.05 mm,
a thickness of the fourth dielectric layer being about 0.05 mm,
a thickness of the fifth dielectric layer being about 0.05 mm, and
a thickness of the sixth dielectric layer being about 0.05 mm.

12. The conductive fabric sensor of claim 1, the sixth dielectric layer covering the entire second surface of the first flexible fabric substrate.

13. The conductive fabric sensor of claim 8, the sixth dielectric layer covering the entire second surface of the first flexible fabric substrate.

14. The conductive fabric sensor of claim 11, the sixth dielectric layer covering the entire second surface of the first flexible fabric substrate.
